#### MINORS OF TREE DISTANCE MATRICES

#### HARRY RICHMAN, FARBOD SHOKRIEH, AND CHENXI WU

ABSTRACT. We prove an identity that relates the principal minors of the distance matrix of a tree, on one hand, to a combinatorial expression involving counts of rooted spanning forests of the underlying tree. This generalizes a result of Graham and Pollak. A variant of this identity applies to the case of edge-weighted trees.

# 1. Introduction

Suppose G = (V, E) is a tree with n vertices. Let D denote the distance matrix of G. In [4], Graham and Pollak proved that

eq:full-det

(1) 
$$\det D = (-1)^{n-1} 2^{n-2} (n-1).$$

This identity is remarkable in that the result does not depend on the tree structure, beyond the number of vertices. The identity ( $\blacksquare$ ) was motivated by a problem in data communication, and inspired much further research on distance matrices. The main result of this paper is to generalize ( $\blacksquare$ ) by replacing det D with any of its principal

The main result of this paper is to generalize ( $\overline{|I|}$  by replacing det D with any of its principal minors. For a subset  $S \subset V(G)$ , let D[S] denote the submatrix consisting of the S-indexed rows and columns of D.

thm:main

**Theorem 1.** Suppose G is a tree with n vertices, and distance matrix D. Let  $S \subset V(G)$  be a nonempty subset of vertices. Then

(2) 
$$\det D[S] = (-1)^{|S|-1} 2^{|S|-2} \left( (n-1) \kappa(G;S) - \sum_{\mathcal{F}_2(G;S)} (\deg^o(F,*) - 2)^2 \right),$$

where  $\kappa(G; S)$  is the number of S-rooted spanning forests of G,  $\mathcal{F}_2(G; S)$  is the set of (S, \*)-rooted spanning forests of G, and  $\deg^o(F, *)$  denotes the outdegree of the \*-component of F.

For definitions of (S,\*)-rooted spanning forests and other terminology, see Section 2. Note that the quantity  $\deg^o(F,*)$  satisfies the bounds

$$1 \le \deg^o(F, *) \le |S|.$$

When S = V is the full vertex set, the set of V-rooted spanning forests is a singleton, consisting of the subgraph with no edges, so  $\kappa(G; V) = 1$ ; and moreover the set  $\mathcal{F}_2(G; V)$  of (V, \*)-rooted spanning forests is empty. Thus (2) recovers the Graham–Pollak identity (I) when S = V.

1.1. Weighted trees. If  $\{\alpha_e : e \in E\}$  is a collection of positive edge weights, the  $\alpha$ -distance matrix  $D_{\alpha}$  is defined by setting the (u,v)-entry to the sum of the weights  $\alpha_e$  along the unique path from uto v. Then

eq:w-full-det

(3) 
$$\det D_{\alpha} = (-1)^{n-1} 2^{n-2} \sum_{e \in E} \alpha_e \prod_{e \in E} \alpha_e$$

 $\det D_{\alpha} = (-1)^{n-1} 2^{n-2} \sum_{e \in E} \alpha_e \prod_{e \in E} \alpha_e.$  This weighted version of the versio of our main theorem.

thm:w-main

**Theorem 2.** Suppose G = (V, E) is a finite, weighted tree with edge weights  $\{\alpha_e : e \in E\}$ , and corresponding weighted distance matrix  $D = D_{\alpha}$ . For any nonempty subset  $S \subset V$ , we have

eq:w-main

(4) 
$$\det D[S] = (-1)^{|S|-1} 2^{|S|-2} \left( \sum_{E(G)} \alpha_e \sum_{\mathcal{F}_1(G;S)} w(T) - \sum_{\mathcal{F}_2(G;S)} (\deg^o(F,*) - 2)^2 w(F) \right).$$

where  $\mathcal{F}_1(G;S)$  is the set of S-rooted spanning forests of G,  $\mathcal{F}_2(G;S)$  is the set of (S,\*)-rooted spanning forests of G, w(T) and w(F) denote the  $\alpha$ -weights of the forests T and F, and  $\deg^o(F,*)$ is the outdegree of the \*-component of F, as above.

Theorem  $\frac{\text{thm:w-main}}{2 \text{ also reduces to Theorem}}$  this main taking all unit weights,  $\alpha_e = 1$ . It is worth observing that depending on the chosen subset  $S \subset V$ , the distances appearing in the submatrix D[S] may ignore a large part of the ambient tree G. We could instead replace G by the subtree  $\operatorname{conv}(S,G)$ consisting of the union of all paths between vertices in S, which we call the convex hull of  $S \subset G$ . To apply formula (2) or (4) "efficiently," we should replace G on the right-hand side with the subtree conv(S,G). However, the formulas as stated are true even without this replacement due to cancellation of terms.

1.2. **Applications.** Given a matrix A, let  $\operatorname{cof} A$  denote the sum of cofactors of A, i.e.

$$\operatorname{cof} A = \sum_{i=1}^{|S|} \sum_{j=1}^{|S|} (-1)^{i+j} \det A_{ij}$$

If A is invertible, then  $\cos A$  is related to the sum of entries of the matrix inverse  $A^{-1}$  by a factor of  $\det A$ , i.e.  $\cot A = (\det A)(\mathbf{1}^{\intercal}A^{-1}\mathbf{1})$ . In [2], Bapat and Sivasubramanian showed the following identity for the sum of cofactors of a distance submatrix D[S] of a tree.

eq:cof-trees

(5) 
$$\operatorname{cof} D[S] = (-2)^{|S|-1} \sum_{T \in \mathcal{F}_1(G;S)} w(T).$$

Using the Bapat–Sivasubramanian identity (b), an immediate corollary to Theorem 2 is the following result.

**Theorem 3.** Suppose G = (V, E) is a finite, weighted tree with edge weights  $\{\alpha_e : e \in E\}$ . Let  $D=D_{\alpha}$  denote the weighted distance matrix of G. For any nonempty subset  $S\subset V$ , we have

$$\frac{\det D[S]}{\cot D[S]} = \frac{1}{2} \left( \sum_{e \in E} \alpha_e - \frac{\sum_{F \in \mathcal{F}_2(G;S)} w(F) k(F,*)^2}{\sum_{T \in \mathcal{F}_1(G;S)} w(T)} \right)$$

where  $k(F, *) = 2 - \deg^{o}(F, *)$ .

## $\Diamond$ add remark / theorem that det/cof is achieved as result of optimization problem $\Diamond$

We remark that the calculation of det D[S] is related to the following quadratic optimization problem: for all vectors  $\mathbf{m} \in \mathbb{R}^{S}$ ,

optimize objective function:  $\mathbf{m}^{\mathsf{T}}D[S]\mathbf{m}$ 

with constraint:  $\mathbf{1}^{\mathsf{T}}\mathbf{m} = 1$ .

**Proposition 4.** If D[S] is a principal submatrix of distance matrix indexed by S, then

$$\frac{\det D[S]}{\operatorname{cof} D[S]} = \max\{\mathbf{m}^\intercal D[S]\mathbf{m}: \mathbf{m} \in \mathbb{R}^S, \, \mathbf{1}^\intercal \mathbf{m} = 1\}$$

where cof D[S] denotes the sum of cofactors of D[S].

This result can be shown using Lagrange multipliers; for details, see Section 4 sec: optimization

**Theorem 5** (Monotonicity of principal minor ratios). If  $A, B \subset V(G)$  are nonempty subsets with  $A \subset B$ , then

$$\frac{\det D[A]}{\cot D[A]} \le \frac{\det D[B]}{\cot D[B]}.$$

**Theorem 6** (Bounds on principal minor ratios). Suppose G = (V, E) is a finite, weighted tree with distance matrix D.

(1) If  $S \subset V(G)$  is nonempty,

$$0 \le \frac{\det D[S]}{\cot D[S]} \le \frac{1}{2} \sum_{E(G)} \alpha_e.$$

(2) If conv(S,G) denotes the subtree of G consisting of all paths between points of  $S \subset V(G)$ ,

$$\frac{\det D[S]}{\operatorname{cof} D[S]} \le \frac{1}{2} \sum_{E(\operatorname{conv}(S,G))} \alpha_e.$$

(3) If  $\gamma$  is a simple path between vertices  $s_0, s_1 \in S$ , then

$$\frac{1}{2} \sum_{e \in \gamma} \alpha_e \le \frac{\det D[S]}{\cot D[S]}$$

**Theorem 7** (Nonsingular minors). Let G be a finite tree with (weighted) distance matrix D, and let  $S \subset V(G)$  be a subset of vertices. If  $|S| \ge 2$  then  $\det D[S] \ne 0$ .

1.3. Previous work. A formula for the inverse matrix  $D^{-1}$  was found by Graham and Lovász in [3].

1.4. **Notation.** G a finite graph, loops and parallel edges allowed, possibly disconnected

E(G) edge set of G

V(G) vertex set of G

 $\mathcal{F}_1(G;S)$  the set of S-rooted spanning forests of G

 $\mathcal{F}_2(G;S)$  the set of (S,\*)-rooted spanning forests of G

### 2. Graphs and matrices

For background on enumeration problems for graphs and trees, see Moon 5.  $\diamond$  decide on reference / references here  $\diamond$ 

Given a graph G = (V, E) with edge weights  $\{\alpha_e : e \in E\}$ , for any edge subset  $A \subset E$  we define the weight of A as

$$w(A) = \prod_{e \in A} \alpha_e.$$

:graphs-matrices

We define the co-weight of A as

$$w(\overline{A}) = \prod_{e \notin A} \alpha_e.$$

By abuse of notation, if H is a subgraph of G, we use  $w(\overline{H})$  to denote  $w(\overline{E(H)})$ .

2.1. **Spanning trees and forests.** A spanning tree of a graph G is a subgraph which is connected, has no cycles, and contains all vertices of G. A spanning forest of a graph G is a subgraph which has no cycles and contains all vertices of G.

Given a set of vertices  $S = \{v_1, v_2, \dots, v_k\}$ , an S-rooted spanning forest of G is a spanning forest which has exactly one vertex  $v_i$  in each connected component. An (S, \*)-rooted spanning forest of G is a spanning forest which has |S| + 1 components, where |S| components each contain one vertex of S, and the additional component is disjoint from S. We call the component disjoint from S the "floating component."

Let

$$\kappa_k(v_1|v_2|\cdots|v_k)$$

denote the number of k-component spanning trees which have a vertex  $v_i$  in each component. If  $S = \{v_1, \ldots, v_k\}$ , then  $\kappa_k(v_1|\cdots|v_k) = \kappa(G/S)$ .

If u, v, w are vertices, then let

$$\kappa_2(uv|w)$$

denote the number of two-forests which have u, v in one component and w in the other component.

**Example 8.** Suppose G is the tree with unit edge lengths shown below.

Let S be the set of three leaf vertices. Then  $\mathcal{F}_1(G;S)$  contains 11 forests, while  $\mathcal{F}_2(G;S)$  contains 19 forests. These are shown in Figures 1 and 2, respectively.

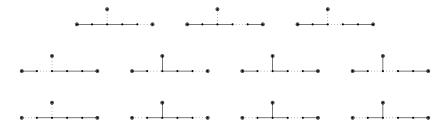

FIGURE 1. Forests in  $\mathcal{F}_1(G;S)$ .

fig:1-forests

2.2. **Laplacian matrix.** Given a graph G = (V, E), let  $L \in \mathbb{R}^{V \times V}$  denote the *Laplacian matrix* of G. If G is a weighted graph with edge weights  $\alpha_e \in \mathbb{R}_{>0}$  for  $e \in E$ , let L denote the weighted Laplacian matrix of G.

Given  $S \subset V$ , let  $L[\overline{S}]$  denote the matrix obtained from L by removing the rows and columns indexed by S.

**Definition 9** (Weighted Laplacian matrix). Given a graph G = (V, E) and edge weights  $\{\alpha_e : e \in E\}$ , the weighted Laplacian matrix  $L_{\alpha} \in \mathbb{R}^{V \times V}$  is defined by

$$(L_{\alpha})_{v,w} = \begin{cases} 0 & \text{if } v \neq w \text{ and } (v,w) \notin E \\ -\alpha_e^{-1} & \text{if } v \neq w \text{ and } (v,w) = e \in E \\ \sum_{e \in N(v)} \alpha_e^{-1} & \text{if } v = w. \end{cases}$$

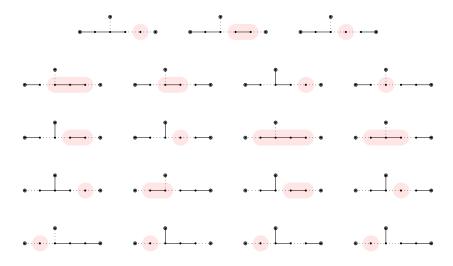

FIGURE 2. Forests in  $\mathcal{F}_2(G;S)$ .

fig:2-forests

For any graph G, let  $\kappa(G)$  denote the number of spanning trees of G. The following theorem is due to Kirchhoff.

thm:matrix-tree

**Theorem 10** (All-minors matrix tree theorem). Let G = (V, E) be a finite graph, and let L denote the Laplacian matrix of G. Then for any nonempty vertex set  $S \subset V$ ,

$$\det L[\overline{S}] = \kappa(G; S).$$

Note that  $\kappa(G; S)$  is also the number of spanning trees of the quotient graph G/S, which "glues together" all vertices in S as a single vertex.

The following result is due to Bapat–Siviasubramanian.

**Theorem 11** (Distance matrix cofactor sums [2]). Given a tree G, let D be the distance matrix of G, and L the Laplacian matrix. Let  $S \subset V(G)$  be a nonempty subset of vertices of G. Then

$$\operatorname{cof} D[S] = (-2)^{|S|-1} \det L[\overline{S}].$$

sec:splits

ec:tree-distance

2.3. **Tree splits.** Given a tree G = (V, E) and an edge  $e \in E$ , the edge deletion  $G \setminus e$  contains two connected components. The components of  $G \setminus e$  splits the vertex set into two disjoint parts  $V = A \sqcup B$ .

Using the implicit orientation on  $e = (e^+, e^-)$ , we let  $(G \setminus e)^+$  denote the component that contains endpoint  $e^+$ , respectively  $(G \setminus e)^-$  and endpoint  $e^-$ .

For any  $e \in E$  and  $v \in V$ , we let  $(G \setminus e)^v$  denote the component of  $G \setminus e$  containing v, respectively  $(G \setminus e)^{\overline{v}} \diamondsuit$  or  $(G \setminus e)^{-v} \diamondsuit$  for the component not containing v.

2.4. Tree distance. Given an edge  $e \in E$  and vertices  $v, w \in V$ , let

$$\delta(e; v, w) = \begin{cases} 1 & \text{if } e \text{ separates } v \text{ from } w, \\ 0 & \text{otherwise.} \end{cases}$$

(Note that  $\delta(e; v, v) = 0$  for any e and v.)

$$\delta(e; v, w) = \begin{cases} 1 & \text{if } e \text{ lies on } v \sim w \text{ path,} \\ 0 & \text{otherwise.} \end{cases}$$

We can express the tree distance d(v, w) as a sum over edges

$$d(v,w) = \sum_{e \in E(G)} \delta(e;v,w) \qquad \text{where } \delta(e;v,w) = \begin{cases} 1 & \text{if $e$ lies on $v \sim w$ path,} \\ 0 & \text{otherwise.} \end{cases}$$

We have the following perspectives on the function  $\delta(e; v, w)$ :

- If we fix v and w, then  $\delta(-; v, w) : E(G) \to \{0, 1\}$  is the indicator function for the unique v w path in G.
- On the other hand if we fix e and v, then the deletion  $G \setminus e$  has two connected components, and  $\delta(e; v, -) : V(G) \to \{0, 1\}$  is the indicator function for the component of  $G \setminus e$  not containing v.

rop:distance-sum

**Proposition 12** (Weighted tree distance). For a tree G = (V, E) with weights  $\{\alpha_e : e \in E\}$ , the weighted distance function satisfies

$$d_{\alpha}(v, w) = \sum_{e \in E} \alpha_e \, \delta(e; v, w).$$

2.5. Outdegree of rooted forest. Given a rooted forest F in  $\mathcal{F}(G; S)$  and  $s \in S$ , let F(s) denote the s-component of F. We define the outdegree  $\deg^o(F, s)$  by

eq:outdeg

(6) 
$$\deg^{o}(F,s) = \#\{e = (a,b) \in E : a \in F(s), b \notin F(s)\}.$$

In words,  $\deg^o(F, s)$  is the number of edges which connect the s-component of F to a different component.

 $\#\{e \in E : e \text{ connects the } s\text{-component of } F \text{ to a different component}\}\$ 

If F is a forest in  $\mathcal{F}_2(G;S)$ , let  $\deg^o(F,*)$  denote the outdegree of the floating component.

lem:outdeg-sum

**Lemma 13.** Suppose G is a tree and  $H \subset G$  is a (nonempty) connected subgraph. Then

$$\sum_{v \in V(H)} (2 - \deg(v)) = 2 - \deg^{o}(H).$$

*Proof.* This is straightforward to check by induction on |V(H)|, with base case |V(H)| = 1: if  $H = \{v\}$  consists of a single vertex, then  $\deg^o(H) = \deg(v)$ .

3. Proofs

In this section we prove Theorem 2.

Outline of proof: given a subset  $S \subset V$  and distance submatrix D[S], we will

- (i) Find vector  $\mathbf{m} \in \mathbb{R}^S$  such that  $D[S]\mathbf{m} = \lambda \mathbf{1} \in \mathbb{R}^S$ .
- (ii) Compute the sum of entries of  $\mathbf{m}$ , i.e.  $\mathbf{1}^{\mathsf{T}}\mathbf{m}$ .
- (iii) Using (i), relate the sum  $1^{T}$ m to the sum of entries of the inverse matrix  $D[S]^{-1}$ :

$$\mathbf{1}^{\mathsf{T}}\mathbf{m} = \lambda(\mathbf{1}^{\mathsf{T}}D[S]^{-1}\mathbf{1}) = \lambda \frac{\cot D[S]}{\det D[S]}.$$

where  $\operatorname{cof} D[S]$  is the sum of cofactors of D[S].

(iv) Use known expression for cof D[S] to compute

$$\det D[S] = \lambda(\operatorname{cof} D[S]) \left(\mathbf{1}^{\mathsf{T}}\mathbf{m}\right)^{-1}.$$

The interesting part of this expression will turn out to be in the constant  $\lambda$ .

**Example 14.** Suppose G is a tree consisting of three paths joined at a central vertex. Let S consist of the central vertex, and the three endpoints of the paths. The corresponding submatrix of the distance matrix is

$$D[S] = \begin{bmatrix} 0 & a & b & c \\ a & 0 & a+b & a+c \\ b & a+b & 0 & b+c \\ c & a+c & b+c & 0 \end{bmatrix}.$$

Following the steps outlined above:

(i) The vector 
$$\mathbf{m} = \begin{bmatrix} -1\\1\\1\\1 \end{bmatrix}$$
 satisfies  $D[S]\mathbf{m} = (a+b+c)\mathbf{1}$ 

- (ii) The sum of entries of  $\mathbf{m}$  is  $\mathbf{1}^{\mathsf{T}}\mathbf{m} = 2$ .
- (iii) We have

$$2 = \mathbf{1}^{\mathsf{T}} \mathbf{m} = \lambda (\mathbf{1}^{\mathsf{T}} D[S]^{-1} \mathbf{1}) = \lambda \frac{\operatorname{cof} D[S]}{\det D[S]}.$$

(iv) The cofactor sum cof D[S] is -8abc, so the determinant is

$$\det D[S] = \lambda \frac{\cot A}{\mathbf{1}^{\mathsf{T}} \mathbf{m}} = (a+b+c)(-8abc)\frac{1}{2} = -4(a+b+c)abc.$$

3.1. Warmup case: S = V.

**Proposition 15.** Let G = (V, E) a tree, and consider the vector  $\mathbf{m} \in \mathbb{R}^V$  defined by

$$\mathbf{m}_v = 2 - \deg v$$
 for each  $v \in V$ .

Then  $\mathbf{1}^{\intercal}\mathbf{m} = \sum_{v \in V} (2 - \deg v) = 2$ .

*Proof.* For any graph,  $\sum_{v \in V} \deg v = 2|E|$ . Since G is a tree, |E| = |V| - 1.

**Proposition 16.** Let **m** be the vector defined above, and let D be the distance matrix of G. Then  $D\mathbf{m} = \lambda \mathbf{1}$  for some constant  $\lambda$ .

*Proof.* It suffices to show that for each edge e, with endpoints  $(e^+, e^-)$ , we have

$$(D\mathbf{m})_{(e^+)} = (D\mathbf{m})_{(e^-)}.$$

We compute

$$(D\mathbf{m})_{(e^+)} - (D\mathbf{m})_{(e^-)} = \sum_{v \in V} (d(v, e^+) - d(v, e^-))(2 - \deg v)$$
$$= \sum_{v \in (G \setminus e)^-} \alpha_e (2 - \deg v) - \sum_{v \in (G \setminus e)^+} \alpha_e (2 - \deg v)$$

since

(7)

eq:12-1

eq:m-vector

-distance-warmup

$$d(v, e^+) - d(v, e^-) = \begin{cases} \alpha_e & \text{if } v \text{ is closer to } e^- \text{ than } e^+, \\ -\alpha_e & \text{if } v \text{ is closer to } e^+ \text{ than } e^-. \end{cases}$$

 $\lozenge$  TO DO: define notation  $(G \setminus e)^{\pm} \diamondsuit$  For each sum in (7), we apply Proposition  $\diamondsuit$  cite  $\diamondsuit$  to obtain

$$\alpha_e \sum_{v \in (G \setminus e)^-} (2 - \deg v) = \alpha_e (2 - \deg^o((G \setminus e)^-)) = \alpha_e.$$

The same identity applies to the sum over  $(G \setminus e)^+$ , so  $(D\mathbf{m})_{(e^+)} = (D\mathbf{m})_{(e^-)}$  as desired.

3.2. **General case:**  $S \subset V$ . Fix a tree G = (V, E) and a nonempty subset  $S \subset V$ .

dfn:m-vector Definition 17. Let  $\mathbf{m} = \mathbf{m}(G; S) \in \mathbb{R}^S$  be defined by

(8) 
$$\mathbf{m}_v = \sum_{T \in \mathcal{F}_1(G;S)} (2 - \deg^o(T,v)) w(T) \quad \text{for each } v \in S.$$

where  $\deg^o(T,v)$  is the outdegree of the v-component of T, (6).

Let 1 denote the all-ones vector.

**Proposition 18.** For **m** defined above, 
$$\mathbf{1}^{\intercal}\mathbf{m} = 2\sum_{T \in \mathcal{F}_1(G;S)} w(T)$$
.

Proof. We have

$$\mathbf{1}^{\mathsf{T}}\mathbf{m} = \sum_{s \in S} \mathbf{m}_s = \sum_{s \in S} \left( \sum_{T \in \mathcal{F}_1(G;S)} (2 - \deg^o(T,s)) w(T) \right)$$
$$= \sum_{T \in \mathcal{F}_1(G;S)} w(T) \left( \sum_{s \in S} \sum_{v \in T(s)} 2 - \deg(v) \right)$$
$$= \sum_{T \in \mathcal{F}_1} w(T) \left( \sum_{v \in V} 2 - \deg(v) \right) = \sum_{T \in \mathcal{F}_1} w(T) \cdot 2.$$

In the second line we apply Lemma  $\Box$  and exchange the outer summations. To obtain the third line, we observe that the vertex sets of T(s) for  $s \in S$  form a partition of V, since T is an S-rooted spanning forest. Finally we again apply Lemma  $\Box$  for the last equality, as  $\deg^o(G) = 0$ .

Corollary 19. If G is a graph with unit edge weights  $\alpha_e = 1$ , then the vector  $\mathbf{m}$  defined in (8) satisfies  $\mathbf{1}^{\mathsf{T}}\mathbf{m} = 2 \kappa(G; S)$ .

**Theorem 20.** With  $\mathbf{m} = \mathbf{m}(G; S)$  defined as in (8),  $D[S]\mathbf{m} = \lambda \mathbf{1}$  for the constant

$$\lambda = \sum_{E(G)} \alpha_e \sum_{\mathcal{F}_1(G;S)} w(T) - \sum_{\mathcal{F}_2(G;S)} (2 - \deg^o(F,*))^2 w(F)$$

where  $\deg^{o}(F, w)$  is the out-degree of the w-component of F (as a spanning forest).

*Proof.* For  $e \in E$  and  $v, w \in V$ , let  $\delta(e; v, w)$  denote the function defined in Section Section Section For any  $v \in S$ , we have

$$(D[S]\mathbf{m})_{v} = \sum_{s \in S} d(v, s)\mathbf{m}_{s}$$

$$= \sum_{s \in S} \left(\sum_{e \in E(G)} \alpha_{e} \,\delta(e; v, s)\right) \left(\sum_{T \in \mathcal{F}_{1}(G; S)} (2 - \deg^{o}(T, s))w(T)\right)$$

$$= \sum_{T \in \mathcal{F}_{1}} w(T) \sum_{e \in E} \alpha_{e} \left(\sum_{s \in S} \delta(e; v, s)(2 - \deg^{o}(T, s))\right)$$

$$= \sum_{T \in \mathcal{F}_{1}} w(T) \sum_{e \in E} \alpha_{e} \left(\sum_{s \in S} \delta(e; v, s) \sum_{u \in T(s)} (2 - \deg(u))\right).$$

$$(9)$$

eq:14-1

We introduce additional notation to handle the double sum in parentheses in (9). Each S-rooted spanning tree T naturally induces a surjection  $\pi_T: V \to S$ , defined by

$$\pi_T(u) = s$$
 if and only if  $u \in T(s)$ .

Using this notation,

$$(D[S]\mathbf{m})_v = \sum_{T \in \mathcal{F}_1} w(T) \sum_{e \in E} \alpha_e \left( \sum_{u \in V} (2 - \deg(u)) \delta(e; v, \pi_T(u)) \right)$$

We will compare the above expression with the one obtained after replacing  $\delta(e; v, \pi_T(u))$  with  $\delta(e; v, u)$ . From  $\diamondsuit$  cite previous prop  $\diamondsuit$ , for any  $v \in V$  and  $e \in E$  we have

$$\sum_{u \in V} (2 - \deg(u))\delta(e; v, u) = 2 - \deg^{o}((G \setminus e)^{\overline{v}}) = 1.$$

Thus

$$(D[S]\mathbf{m})_v - \sum_{T \in \mathcal{F}_1} w(T) \sum_{e \in E} \alpha_e = \sum_{T \in \mathcal{F}_1} w(T) \sum_{e \in E} \alpha_e \sum_{u \in V} (2 - \deg(u)) \left(\delta(e; v, \pi_T(u)) - \delta(e; v, u)\right)$$

When  $e \in E$  and  $v \in V$  are fixed,  $u \mapsto \delta(e; v, u)$  is the indicator function of one component of the principal cut  $G \setminus e$ . Recall that  $\delta(e; \cdot, \cdot)$  is a (0, 1)-valued pseudometric on V. We have

$$\delta(e; v, \pi_T(u)) - \delta(e; v, u) = \begin{cases} 0 & \text{if } \delta(e; \pi_T(u), u) = 0\\ 1 & \text{if } \delta(e; \pi_T(u), u) = 1 \text{ and } \delta(e; v, \pi_T(u)) = 1\\ -1 & \text{if } \delta(e; \pi_T(u), u) = 1 \text{ and } \delta(e; v, \pi_T(u)) = 0 \end{cases}$$

Now consider varying u over all vertices, when e, T, and v are fixed. We have the following three cases:

Case 1: if  $e \notin T$ , then u and  $\pi_T(u)$  are on the same side of the principal cut  $G \setminus e$ , for every vertex u. In this case  $\delta(e; v, \pi_T(\cdot)) - \delta(e; v, \cdot) = 0$ .

Case 2: if  $e \in T(s_0)$  and  $s_0$  is separated from v by e, then  $\delta(e; v, \pi_T(\cdot)) - \delta(e; v, \cdot)$  is the indicator function for the floating component of  $T \setminus e$ .

Case 3: if  $e \in T(s_0)$  and  $s_0$  is on the same component as v from e, then  $\delta(e; v, \pi_T(\cdot)) - \delta(e; v, \cdot)$  is the negative of the indicator function for the floating component of  $T \setminus e$ .

FIGURE 3. Edge  $e \in T(s_0)$  with  $\delta(e; v, s_0) = 1$  (left) and  $\delta(e; v, s_0) = 0$  (right). The floating component of  $T \setminus e$  is highlighted.

Thus when multiplying the above term by  $(2-\deg(u))$  and summing over all vertices u, we obtain

$$\sum_{u \in V} (2 - \deg(u))(\delta(e; v, \pi_T(u)) - \delta(e; v, u)) = \begin{cases} 0 & \text{if } e \not\in T, \\ 2 - \deg^o(T \setminus e, *) & \text{if } e \in T(s_0) \text{ and } \delta(e; v, s_0) = 1, \\ -(2 - \deg^o(T \setminus e, *)) & \text{if } e \in T(s_0) \text{ and } \delta(e; v, s_0) = 0. \end{cases}$$

Thus

$$\frac{\overline{\mathbf{q}:1}}{(10)} \quad (D[S]\mathbf{m})(v) - \sum_{T \in \mathcal{F}_1} w(T) \sum_{e \in E} \alpha_e$$

$$= \sum_{T \in \mathcal{F}_1} w(T) \sum_{s_0 \in S} \left( \sum_{\substack{e \in T(s_0) \\ \delta(e:v,s_0) = 1}} \alpha_e(2 - \deg^o(T \setminus e, *)) - \sum_{\substack{e \in T(s_0) \\ \delta(e:v,s_0) = 0}} \alpha_e(2 - \deg^o(T \setminus e, *)) \right).$$

We now rewrite the above expression in terms of  $\mathcal{F}_2(G; S)$ , observing that the deletion  $T \setminus e$  is an (S, \*)-rooted spanning forest of G, if  $e \in T$ , and that the corresponding weights satisfy

$$w(F) = \alpha_e \cdot w(T)$$
 if  $F = T \setminus e$ .

Thus

Thus

$$\frac{(eq: 1)}{(I0)} = \sum_{F \in \mathcal{F}_2} w(F)(2 - \deg^o(F, *)) \sum_{T \in \mathcal{F}_1} \sum_{s_0 \in S} \left( \sum_{\substack{e \in T(s_0) \\ \delta(e; v, s_0) = 1}} \mathbb{1}(F = T \setminus e) - \sum_{\substack{e \in T(s_0) \\ \delta(e; v, s_0) = 0}} \mathbb{1}(F = T \setminus e) \right)$$

$$= \sum_{F \in \mathcal{F}_2} w(F)(2 - \deg^o(F, *)) \left( \#\{T \in \mathcal{F}_1 : F = T \setminus e \text{ for some } e \in T(s_0), \, \delta(e; v, s_0) = 1\} \right)$$

$$- \#\{T \in \mathcal{F}_1 : F = T \setminus e \text{ for some } e \in T(s_0), \, \delta(e; v, s_0) = 0\} \right)$$

Next, we note that  $F = T \setminus e$  is equivalent to  $T = F \cup e$ , and in particular this only occurs when we choose the edge e to be in the floating boundary  $\partial F(*)$ :

$$v \xrightarrow{F(*)} v \xrightarrow{e} F(*)$$

FIGURE 4. Edge  $e \in \partial F(*)$  with  $\delta(e; v, F(*)) = 0$  (left) and  $\delta(e; v, F(*)) = 1$  (right). The floating component F(\*) is highlighted.

Now for any  $e \notin F$ , let  $\delta(e; v, F(*)) = \delta(e; v, x)$  for any  $x \in F(*)$ , i.e.

$$\delta(e; v, F(*)) = \begin{cases} 1 & \text{if } e \text{ lies on path from } v \text{ to } F(*), \\ 0 & \text{otherwise.} \end{cases}$$

The condition  $F = T \setminus e$  for some  $e \in T(s_0)$  with  $\delta(e; v, s_0) = 1$  (resp.  $\delta(e; v, s_0) = 0$ ) is equivalent to  $T = F \cup e$  for some  $e \in \partial F(*)$  with  $\delta(e; v, F(*)) = 0$  (resp.  $\delta(e; v, F(*)) = 1$ ). Thus

$$(\stackrel{\mathsf{eq}\,:1}{\mathsf{ID}}) = \sum_{F \in \mathcal{F}_2} w(F)(2 - \deg^o(F, *)) \Bigg( \# \{ e \in \partial F(*) : \delta(e; v, F(*)) = 0 \}$$
 
$$- \# \{ e \in \partial F(*) : \delta(e; v, F(*)) = 1 \} \Bigg).$$

Finally, we observe that for any forest F in  $\mathcal{F}_2(G;S)$ , there is exactly one edge e in the boundary  $\partial F(*)$  of the floating component which satisfies  $\delta(e;v,F(*))=1$ , namely the unique boundary edge on the path from the floating component F(\*) to v. The previous expression (10) simplifies as

$$\#\{e \in \partial F(*): \delta(e; v, F(*)) = 1\} = 1 \qquad \text{and} \qquad \#\{e \in \partial(F, *): \delta(e; v, F(*)) = 0\} = \deg^o(F, *) - 1.$$

$$\begin{split} \binom{|\text{eq}:1}{10} &= \sum_{F \in \mathcal{F}_2} w(F) (2 - \deg^o(F,*)) \Big( (\deg^o(F,*) - 1) - (1) \Big) \\ &= - \sum_{F \in \mathcal{F}_2} w(F) (2 - \deg^o(F,*))^2. \end{split}$$

as desired.  $\Box$ 

Figure 5. Components rooted in  $S(G \setminus e)^{\overline{v}}$ .

# $\Diamond$ MOVE TO REMARK? If $e \in \text{conv}(G,S)$ , then $S(G \backslash e)^{\overline{v}}$ is nonempty and $\Diamond$

**Remark 21.** The set  $\mathcal{F}_2(G; S)$  of (S, \*)-rooted spanning forests of G can be partitioned into two types: "active" and "inactive".

$$\mathcal{F}_2(G;S) = \mathcal{F}_2^{in}(G;S) \sqcup \mathcal{F}_2^{out}(G;S),$$

where

$$\mathcal{F}_{2}^{in}(G; S) = \{ F \in \mathcal{F}_{2}(G; S) \text{ such that } \deg^{o}(*, F) \geq 2 \},$$
  
 $\mathcal{F}_{2}^{out}(G; S) = \{ F \in \mathcal{F}_{2}(G; S) \text{ such that } \deg^{o}(*, F) = 1 \}.$ 

Remark 22. A key step in the above proof is the use of the map

$$E(G) \times \mathcal{F}_1(G; S) \mapsto S \sqcup \{\text{error}\}\$$

defined by

$$(e,T)\mapsto \begin{cases} s & \text{if } e\in T(s),\\ \text{error} & \text{if } e\not\in T. \end{cases}$$

**Remark 23.** For a given spanning forest  $F \in \mathcal{F}_2(G; S)$ , there are exactly  $\deg^o(F, *)$ -many choices of pairs  $(T, e) \in \mathcal{F}_1(G; S) \times E(G)$  such that  $F = T \setminus e$ . Consider the "deletion" map

$$E(G) \times \mathcal{F}_1(G;S) \to \mathcal{F}_2(G;S) \sqcup \mathcal{F}_1(G;S)$$

defined by ...

$$(e,T) \mapsto \begin{cases} T \setminus e & \text{if } e \in T, \\ T & \text{if } e \notin T. \end{cases}$$

For a forest F in  $\mathcal{F}_2(G;S)$ , the preimage under this map has  $\deg^o(F,*)$  elements.

There is an associated "union" map

$$E(G) \times \mathcal{F}_2(G;S) \longrightarrow \mathcal{F}_1(G;S) \sqcup \mathcal{F}_2(G;S)$$

defined by

$$(e,F) \mapsto \begin{cases} F \cup e & \text{if } e \notin F, \\ F & \text{if } e \in F \end{cases}$$

### 4. Optimization: Quadratic programming

**Proposition 24.** If D[S] is a principal submatrix of a distance matrix indexed by S, then

$$\frac{\det D[S]}{\cot D[S]} = \max\{\mathbf{m}^{\intercal}D[S]\mathbf{m} : \mathbf{m} \in \mathbb{R}^{S}, \ \mathbf{1}^{\intercal}\mathbf{m} = 1\}$$

where  $\operatorname{cof} D[S]$  denotes the sum of cofactors of D[S].

**Proposition 25.** If D[S] is a principal submatrix of a distance matrix indexed by S, then

$$\frac{\det D[S]}{\cot D[S]} = \max\{\mathbf{m}^{\mathsf{T}} D\mathbf{m} : \mathbf{m} \in \mathbb{R}^{V}, \mathbf{1}^{\mathsf{T}} \mathbf{m} = 1, \mathbf{m}_{v} = 0 \text{ if } v \notin S\}$$

where  $\operatorname{cof} D[S]$  denotes the sum of cofactors of D[S].

The gradient of the objective function is  $2D[S]\mathbf{m}$ , and the gradient of the constraint is 1. By the theory of Lagrange multipliers, the optimal solution  $\mathbf{m}^*$  is a vector satisfying

$$D[S]\mathbf{m}^* = \lambda \mathbf{1}$$
 for some  $\lambda \in \mathbb{R}$ .

The constant  $\lambda$  is in fact the optimal objective value, since

$$(\mathbf{m}^*)^{\mathsf{T}}D[S]\mathbf{m}^* = (D[S]\mathbf{m}^*)^{\mathsf{T}}\mathbf{m}^* = \lambda(\mathbf{1}^{\mathsf{T}}\mathbf{m}^*) = \lambda.$$

sec:optimization

(The above computation uses the fact that D[S] is a symmetric matrix, and the given constraint  $\mathbf{1}^{\mathsf{T}}\mathbf{m} = 1$ .) On the other hand, assuming D[S] is invertible we have  $\mathbf{m}^* = \lambda(D[S]^{-1}\mathbf{1})$ , so that

$$1 = \mathbf{1}^{\mathsf{T}} \mathbf{m}^* = \lambda (\mathbf{1}^{\mathsf{T}} D[S]^{-1} \mathbf{1}) = \lambda \frac{\operatorname{cof} D[S]}{\det D[S]}.$$

Thus the optimal objective value is  $\lambda = \frac{\det D[S]}{\cot D[S]}$ 

#### 5. Physical interpretation

If we consider G as a network of wires with each edge containing a unit resistor, which is grounded at all nodes in S, then  $\mathbf{m}_S$  records the currents flowing to S when current is added on  $V \setminus S$  in the amount  $2 - \deg v$  for each  $v \notin S$ .

5.1. Alternate proof. Let 1 denote the all-ones vector. When we choose a subset  $S \subset V(G)$ , we no longer have a single "obvious" replacement for  $\mathbf{m}$  inside  $\mathbb{R}^S$ . Instead, we can take an average over S-rooted spanning forests.

In the outline above, our first goal is to find a "special" vector  $\mathbf{m} \in \mathbb{R}^S$  satisfying  $D[S]\mathbf{m} = \lambda \mathbf{1}$ . We can approach this first goal as follows: consider  $\mathbb{R}^S$  inside the larger vector space  $\mathbb{R}^V = \mathbb{R}^S \oplus \mathbb{R}^{V \setminus S}$ , and we wish to find vectors  $\mathbf{n}_i \in \mathbb{R}^V$  satisfying  $\pi_S(D\mathbf{n}_i) = \lambda_i \mathbf{1}$ . By finding sufficiently many such vectors  $\mathbf{n}_i$ , we can hope to find a linear combination that lies inside  $\mathbb{R}^S \oplus \{0\}$ .

prop:n-vector

**Proposition 26.** Suppose  $v \in V \setminus S$ . For each  $s_j \in S$ , let  $\mu(v, s_j) = current$  flowing to  $s_j$  when G is grounded at S and one unit of current enters G at v. Explicitly,

$$\mu(v,s) = \frac{\# \ of \ S\text{-rooted spanning forests of } G \ whose \ s_{j}\text{-component contains } v}{\# \ of \ S\text{-rooted spanning forests of } G}$$

$$= \frac{\sum_{\mathcal{F}_{1}(G/S)} \mathbb{1}(v \in T(s))}{\kappa(G/S)}$$

$$= \frac{\kappa_{r}(s_{1}|\cdots|s_{j}v|\cdots|s_{r})}{\kappa_{r}(s_{1}|\cdots|s_{r})}$$

Consider the vector  $\mathbf{n} = \mathbf{n}(G; S, v) \in \mathbb{R}^V$  defined by

$$\mathbf{n}_v = 1, \quad \mathbf{n}_s = -\mu(v, s) \text{ if } s \in S, \quad \mathbf{n}_w = 0 \text{ if } w \notin S \cup v$$

Then  $D\mathbf{n}$  is constant on S, i.e.  $\pi_S(D\mathbf{n}) = \lambda \mathbf{1}$  for some  $\lambda$ .

*Proof sketch.* For any  $s, s' \in S$ , consider tracking the value of  $D\mathbf{n}$  along path from s to s'. The value of  $D\mathbf{n}$  changes according to current flow in the corresponding network, i.e.  $D\mathbf{n}$  records electrical potential. By assumption S is grounded, so  $D\mathbf{n}$  takes the same value at s and s'.

**Theorem 27.** Let G be a tree, S a nonempty subset of vertices, and  $D[\underline{S}]$  the corresponding submatrix of the distance matrix. Suppose  $\mathbf{m} = \mathbf{m}(G;S) \in \mathbb{R}^S$  is defined by (8);

$$\mathbf{m}(G; S)_v = \sum_{T \in \mathcal{F}_1(G; S)} \sum_{w \in T_v} (2 - \deg w) = \sum_{T \in \mathcal{F}_1(G; S)} 2 - \deg^o(T, v).$$

Then  $D[S]\mathbf{m} = \lambda \mathbf{1}$  for some constant  $\lambda$ .

*Proof.* The vector  $\mathbf{m} = \mathbf{m}(G; S)$  can be expressed as a linear combination

$$\begin{split} \mathbf{m}(G;S) &= \kappa(G;S) \left( \sum_{v \in V} (2 - \deg v) \boldsymbol{\delta}(v) - \sum_{v \in V \setminus S} (2 - \deg v) \mathbf{n}(G;S,v) \right) \\ &= \kappa(G;S) \left( \mathbf{m}(G;V) - \sum_{v \in V \setminus S} (2 - \deg v) \mathbf{n}(G;S,v) \right) \end{split}$$

♦ TODO: elaborate on this equation ↑ From Proposition brop:m-distance-warmup | 16 we know that  $D\mathbf{m}(G;V)$  is constant on V, and from Proposition brop:m-vector | 16 we know that  $D\mathbf{n}(G;S,v)$  is constant on S. Hence by linearity,  $D\mathbf{m}(G;S)$  is constant on S.

**Proposition 28.** Let G = (V, E) be a tree, and  $S \subset V$ . Suppose we label  $S = \{s_1, \ldots, s_r\}$  and  $V \setminus S = \{t_1, \ldots, t_{n-r}\}$ . For each  $t_i \in V \setminus S$ , consider  $\mathbf{f}_i \in \mathbb{R}^V$  defined by

### Example 29. If

$$D[S \cup t] = \begin{bmatrix} 0 & a & b & c \\ a & 0 & a+b & a+c \\ b & a+b & 0 & b+c \\ c & a+c & b+c & 0 \end{bmatrix}$$

then

$$\begin{bmatrix} 0 & a & b & c \\ a & 0 & a+b & a+c \\ b & a+b & 0 & b+c \\ c & a+c & b+c & 0 \end{bmatrix} \begin{bmatrix} ab+ac+bc \\ -bc \\ -ac \\ -ab \end{bmatrix} = \begin{bmatrix} -3abc \\ -abc \\ -abc \\ -abc \end{bmatrix}$$

#### 6. Examples

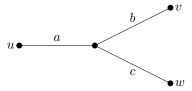

**Example 30.** Suppose G is a tree consisting of three paths joined at a central vertex. Let S consist of the central vertex, and the three endpoints of the paths. The corresponding minor of the distance matrix is

$$D[S] = \begin{bmatrix} 0 & a & b & c \\ a & 0 & a+b & a+c \\ b & a+b & 0 & b+c \\ c & a+c & b+c & 0 \end{bmatrix} \sim \begin{bmatrix} 0 & a & b & c \\ a & -a & a & a \\ b & b & -b & b \\ c & c & c & c & -c \end{bmatrix} \sim \begin{bmatrix} 0 & a & b & c \\ a & -2a & 0 & 0 \\ b & 0 & -2b & 0 \\ c & 0 & 0 & -2c \end{bmatrix}.$$

The determinant is

$$\det D[S] = -4(a+b+c)abc.$$

**Example 31.** Suppose  $\Gamma$  is a tripod with lengths a, b, c and corresponding leaf vertices u, v, w.

Let  $S = \{u, v, w\}$ . Then

$$D[S] = \begin{bmatrix} 0 & a+b & a+c \\ a+b & 0 & b+c \\ a+c & b+c & 0 \end{bmatrix}.$$

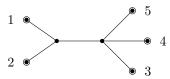

and

$$\det D[S] = 2(a+b)(a+c)(b+c) = 2((a+b+c)(ab+ac+bc) - abc).$$

The "special vector" that satisfies  $D[S]\mathbf{m} = \lambda \mathbf{1}$  in this example is

$$\mathbf{m} = \begin{bmatrix} a(b+c) & b(a+c) & c(a+b) \end{bmatrix}^{\mathsf{T}}.$$

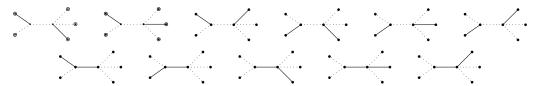

**Example 32.** Suppose  $\Gamma$  is the tree with unit edge lengths shown below, with five leaf vertices.

Let S denote the set of five leaf vertices. Then

$$D[S] = \begin{bmatrix} 0 & 2 & 3 & 3 & 3 \\ 2 & 0 & 3 & 3 & 3 \\ 3 & 3 & 0 & 2 & 2 \\ 3 & 3 & 2 & 0 & 2 \\ 3 & 3 & 2 & 2 & 0 \end{bmatrix}.$$

Forests in  $\mathcal{F}_1(G;S)$ :

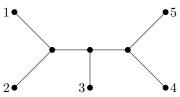

Forests in  $\mathcal{F}_2(G;S)$ :

and

$$\det D[S] = 368 = (-1)^4 2^3 \left( 6 \cdot 11 - \left( 3 \cdot 1^2 + 2 \cdot 2^2 + 1 \cdot 3^2 \right) \right)$$

**Example 33.** Suppose  $\Gamma$  is the tree with unit edge lengths shown below, with five leaf vertices and three internal vertices.

Let S denote the set of five leaf vertices. Then

$$D[S] = \begin{bmatrix} 0 & 2 & 3 & 4 & 4 \\ 2 & 0 & 3 & 4 & 4 \\ 3 & 3 & 0 & 3 & 3 \\ 4 & 4 & 3 & 0 & 2 \\ 4 & 4 & 3 & 2 & 0 \end{bmatrix}$$

and

$$\det D[S] = 864 = (-1)^4 2^3 \left(7 \cdot 21 - (14 \cdot 1^2 + 4 \cdot 2^2 + 1 \cdot 3^2)\right)$$
